Review of “Eco-evolutionary dynamics further weakens mutualistic interaction and coexistence under population decline” submitted to PCI Ecology by A. Weinbach et al.

One reviewer and myself have read the revision of the paper. The reviewer has nothing important to add (except a few minor comments, questions and precision requests). I appreciate a lot your effort to present your model in a more general and comprehensive version. In particular, I find that the introduction is now very good, and that your results are now particularly well presented. Yet, I have to admit I am a bit disappointed that you decided not to change the presentation of the core of the model and stuck to the pollen-pollinator model. On the one hand, I understand that you wanted to keep a less abstract model which can indeed help the reader to understand what is happening. On the other hand, the generality of the model can be missed by readers. In addition, as suggested in the first round of review, if the goal is to modelize a plant-pollinator system, then there is good chance that the equation you proposed are not correct, or under very stringent assumptions only (see Fishman and Hadany 2010 TPB), or for rare plant-pollinator system (for instance geitonogamy). Anyway, I respect your choice, I simply regret a bit that your model might not be understood and read as general as it is (but I will try to emphasize it in my recommendation). As I find your paper interesting, I would be happy to recommend your paper, pending minor corrections requested by the reviewer, and some other minor comments below from myself.

Thank you for all your comments and remarks and your will to recommend our manuscript pending minor modifications. We took them into account to further increase the quality of our manuscript. We understand your remark concerning the limitations of our model as applied to a pollination system. We however feel that the pollination angle would actually help the reader by making the disturbance discussion less abstract (given the current important focus on the pollination crisis). We have proposed modifications in the discussion parts to better specify how our model can be viewed as general, and the limitations of specifying it as a pollination model. We also compare our work to other models at lines 264-287 and 292-300. We insist in the discussion on the generality of our model e.g. at lines 255-257.

1 Minor comments

- L31: “as illustrated in [9]”: be more specific here, please give a quick idea of the content of this paper. It should be obvious for the reader that this paper is relevant in the current context of the present paper.

  We rephrased this part at lines 28-35.

- L91: “plant-dependent” (check whether a “-” is necessary or not).

  The text has been modified.

- L92 and throughout the paper: please be consistent about the format of figures referencing. I would suggest using capital “F” throughout the paper, using “Fig.” abbreviation, and “( - )” when appropriate. • L100: I do not think the word “dynamical” is necessary (an equilibrium is necessarily defined within a dynamical system?).

  The text has been homogenised.
L102: “implies”: is there a proof of this implication? If so, where is it given?

Precisions have been added to that paragraph at lines 103-105.

L122: no dot after “modes”

The text has been modified.

L173: Can you explain why you decided to only study concave trade-offs? For biological reasons? Technical and methodological reasons? If biological, then why didn’t you consider only \( s > 1 \) from the beginning? If not biological, what other reasons?

Precisions have been given at lines 191-193.

What conclusions can be drawn from the study of convex functions? Any biological interpretation, prediction about the evolution of mutualistic interactions?

As explained in the paragraph from lines 183 to 191, convex trade-offs will lead to extreme situations with only one growth mode favoured and either mandatory mutualism or no more interaction.

First and second paragraph of section 4: I found these two paragraphs a bit messy as there are partially redundant information, but their goal is different. I have no definitive suggestion about how you could improve the organization of these two paragraphs, but I think it would be important to give it a try since it is here that the reader is introduced in the results of the model. It is important that the reader is not lost in the beginning.

We have rewritten these two paragraph to clarify their structure.

L189: Figure 4a I suppose?

The text has been modified.

L. 192-193: I guess when you decrease the pollinator growth rate in Fig. 4, you assume that the new starting point is at ecological equilibrium, right? I would suggest to add this point explicitly in the text (it helped me to understand how you did your calculations).

This precision has been added at lines 213-215.

Fig.4b (linked to the previous comment): I think what would help a lot understanding what you did would be to add an arrow also on the plant Figure since, as far as I understand correctly, the plant population also moves on the left, by exactly the same distance and direction than arrow (3) on Fig. 4a.

We have added the arrows on the right part of the figure.

I would strongly suggest to add information about plant density in Fig.5: I imagine Figures on plant density should not vary a lot, but I think it is important for the reader to have a clear idea of what’s happening to plants.

We have followed this advice and we now provide a figure showing variations in plant densities in the supplementary materials and refer to it in the main text at lines 243-244.

L206: It is not immediately clear how you define the “coexistence domain” and how the reader should see its increase in the figure. I would suggest to help the reader a little more here, in particular by defining what you mean by this “domain” and how it is depicted on the figure. It is important because at first, when looking at the size of the dashed line and the position of the red dot, I concluded exactly the reverse than your text: when \( s \) increases, the larger the region where pollinator would go extinct when attempting restoration.
We have added this precision at lines 228-233.

- L223: “selects further decreases”: please rephrase (I suspect a typo).

The text has been modified.
I have only few minor comments in order to improve the new version of the manuscript. My main comments concern, first, the removal of repetitions in Sections A and B, and second, Section C added in Supplementary Material, which is a mathematical analysis of a particular case. It is not clear why this particular case is treated and I suggest to add some explanations about that.

Thank you very much for these comments and suggestions. We have modified our supplementary materials to follow your recommendations and have modified the main text accordingly.

Comments

- eq. (6): write \( r_P(\alpha) \) instead of \( r_P \);

The equation has been modified.

- Supp. Mat.: some repetitions occur in Sections A and B. I suggest to merge these 2 sections in order to make them clearer.

The two sections have been merged and homogenised.

- Supp. Mat., top of p.2: Check the english grammar: I think that “the dynamic is” should be replaced by “the dynamics are”. Moreover “zeros” should be “zero”.

The text has been corrected.

- Eq (B8): \( \hat{\epsilon}^2 \rightarrow \hat{\alpha}^2 \)

The equation has been modified.

- Supp. Mat.: Check all equation references and take into account the change of numbering. For example (old) equation (5) is now equation (7). At the beginning of Section “Conditions for invasibility”: the trade-off is not defined in Appendix A, but in eq. (6) in the main article. Eq (C3) does not exist; I think you wanted to refer to (C19).

The text has been modified.

- I think that Section C in the current state is not really useful. My suggestion: Either explain clearly in the main text that \( s = 2 \) appears numerically as a threshold for the existence of 2 singular strategies and notice that the mathematical proof is not easy to derive but that we can however prove it in a particular case. Moreover add a sentence like “We prove in this section that \( s = 2 \) is a threshold for the existence of a second singular strategy in the case \( r_A = 0 \) for concave trade-off.” as introduction of Section C. Or delete this section.

We modified the appendix according to your suggestion and added precisions in the main text at lines 178-182.
